Through the Melbourne Mining Integrator (MMI), the University of Melbourne works with explorers, miners and mining equipment, technology and service (METS) providers to tackle some of the sector’s most challenging problems.

The MMI assembles multidisciplinary teams from across the University to leverage our extensive knowledge of the mining industry, integrating new perspectives and different approaches more commonly applied in other industries such as defence, manufacturing, finance and IT.

Our considerable expertise in machine learning and artificial intelligence, data analytics, social trends, environmental management, logistics and financial assessment are already being applied within the mining industry.

Working closely with our partners, we can provide end-to-end solutions – from shaping technological problems, analysing the solutions through simulation, through to testing prototypes in our facilities and in the field.

Through the MMI we are uniquely positioned to provide an integrated view of the mining value chain and also harness the unique capabilities across Australia’s most successful universities.

**HOW TO ENGAGE WITH US**

**Consulting and Technology Strategy**

- Research, systems engineering and technology development
- Survey and assess emerging technologies
- Developing R&D projects in your company
- Technology evaluation
- Technology implications for policy

**Research Projects**

- Contracted and collaborative research
- Individual experts or teams of researchers

**Student Projects, Internships and Placement**

- Undergraduate students could be working on your problems
- Our PhD students undertake an internship in your company
- Postdocs could be placed in your organisation for 1-3 years

**THREE KEY PROGRAMS OF RESEARCH**

- **Next generation digital mining** – new techniques to analyse the large volumes of exploration and mine data to optimise mine operation and maximise value
- **Mine planning and agile logistics** – new techniques and mine designs to optimise operations along mining supply chains incorporating real-time responsiveness
- **Process productivity** – improving the performance of existing unit operations and developing new systems incorporating latest technologies
This research program aims to develop and deploy new techniques for analysing the large volumes of data that will be produced in the future and use this analysis to improve mine operations.

Mine sites are increasingly moving to remote and autonomous operation with remote sensing, robotics and autonomous infrastructure. In this setting, more data will be available than ever, from the increased monitoring of a material’s characteristics as it moves from pit to plant and real-time knowledge of the location and status of equipment and stockpiled ore.

Next generation digital mining techniques have the capacity to:

» facilitate reconciliation between expected and realised outcomes;
» communicate the overall state, and predicted future state, of operations to miners in real time, given large volumes of data from varying sources; and
» continually revise ore body models in terms of composition and processing characteristics as new data arises.

The MMI has expertise and unparalleled critical mass in data mining, machine learning, simulation and modelling, remote sensing, stream data mining, decision analytics and real options analysis.
Life-of-mine (LOM) planning for the Pilbara iron ore network

MMI has developed life-of-mine (LOM) planning techniques for an open-pit iron ore mine network in Western Australia’s Pilbara region. New, more efficient and scalable algorithms developed for a tier-one miner are delivering a step change in the speed of options made available to mine planners, solving LOM planning problems much faster than previously possible. The approach helps optimise multiple objectives and decisions on stockpiling, practical mining constraints and financial modelling for capital expenditure. The techniques also help to free millions of dollars in cash flow and ensure an even-greater net present value over the life of the mine.
**PROCESS PRODUCTIVITY**

The mining industry is constantly being challenged to improve safety and increase the productivity of its assets, while simultaneously aiming to maintain or improve product quality.

This research program aims to optimise the productivity of current assets and also develop and deploy new technologies for the extraction of metals from their ores. Advanced processing techniques have the potential to significantly improve the efficiency of mining operations. The use of column arrangements, for example, in place of mixer-settlers in solvent extraction processes can reduce capital costs and land and operational requirements, while increasing plant throughput.

Improved chemicals and models that describe chemical interactions with target metals can improve plant efficiency and metal yields while potentially reducing water and energy requirements, significantly reducing operating costs and the environmental footprint of an operation.

The MMI has expertise in advanced polymers, flocculation, solid-liquid separation, rheology control and flotation, sludge thickening and dewatering, and advanced equipment and solvents for solvent extraction processes. We also work in energy-efficient comminution solutions and mineral recovery through flotation.

**CASE STUDY**

**Solvent extraction**

MMI has developed advanced techniques for the extraction of metals from their ores based on the use of pulsed columns – a game-changing alternative to mixer-settlers. Our advanced chemical and thermodynamic models have improved plant efficiency and metal yields while dramatically reducing water and energy requirements. After demonstrating a prototype based on pulsed columns, the technique has been successfully scaled up and deployed at a major mine site, halving water use.

**CASE STUDY**

**Minerals processing**

The university has developed novel techniques in minerals processing using polymeric reagents in solid/liquid separation and froth flotation. Key outcomes include demonstrating that underflow density can be increased while reducing rheological (flow) properties to reduce pumping energy to tailings dams. This work has led to improved grade and recovery of fine iron and copper ores in flotation.

**OUR RESEARCH TEAM**

**Dr Kathryn Mumford**

Research Team Leader

Kathryn is a senior lecturer in the Department of Chemical and Biomolecular Engineering at the University of Melbourne whose research has delivered breakthroughs in separations processes, specifically ion exchange, solvent absorption and solvent extraction technologies.

**Professor Peter Scales**

- Particulate fluids processing
- Wastewater processing
- Rheology (used in ore processing) and flocculation

**Dr Anthony Stickland**

- Solid-liquid separation
- Suspension rheology

**Professor George Franks**

- Mineral processing, flocculation and colloids
- Surface chemistry
- Mining reagents and flotation

**Dr Iman Shames**

- Control theory and systems

**PARTNER AND COLLABORATE WITH US**

Contact: Associate Professor Adrian Pearce, Melbourne School of Engineering
